

Model Context Protocol (MCP) is a fundamental principle for working with Large Language Models (LLMs). It defines how much and what kind of input (context) should be provided to the model so that it can generate accurate and high-quality responses. Since LLMs predict the next word based on the given context, controlling the quality, structure, and size of this context is essential. MCP ensures the input is well-organized to improve the model's output reliability and relevance.
